RGB Interface Mode Selection

The Ilitek ILI9341V driver IC is user configurable for DE Mode and SYNC mode RGB interface.

DE Mode is enabled when the RCM [1:0] bits of B0h command are set to “10”, and DE signal is high for valid pixel data. Data is clocked in using rising edge of DOTCLK signal. DE mode is recommended to enable the ILI9341V driver IC to synchronize the display image on TFT panel without depending on specific horizontal and vertical sync timing from host controller.

SYNC mode is enabled when the RCM [1:0] bits of B0h command are set to “11”, DE signal is ignored, and HSYNC and VSYNC signals are used to explicitly define the horizontal and vertical sync timing to synchronize the display image on TFT panel. Data is clocked in using rising edge of DOTCLK signal. Any change to the HSYNC or VSYNC values may prevent the image from correctly appearing on the display.

ILI9341V supports several pixel formats that can be selected by DPI [2:0] bits of “Pixel Format Set (3Ah)” and RIM bit of F6h command.

RCM[1:0]		RIM	DPI[2:0]			RGB Interface Mode	RGB Mode	Used Pins
1	0	0	1	1	0	18-bit RGB interface (262K colors)	DE Mode Valid data is determined by the DE signal	VSYNC, HSYNC, DE, DOTCLK, D[17:0]
